**Basic Abstract :**

WO9210264 A

A distn. appts. evaporates and subsequently condenses a liq. It comprises a number of flat bags formed of a thin-film material, e.g. plastic, placed one against the other. The bags serve as heat exchangers between a vaporising liq. flowing along their exterior surfaces and a condensing vapour flowing inside the bags. A compressor increases the temp. and pressure of the generated vapour before it is directed to the inside of the bags. At the upper end of each bag is a honeycomb-structured end strip having the width of the bag and contg. parallel feeding ducts sepd. from each other by partition walls. The ducts distribute the liq. to be evaporated over the entire width of the bag.

The end strip (4) consists of a honeycomb, made from three plastic honeycomb boards. In each

board, the space between opposite walls is divided by transverse, mutually parallel partition walls (24) into parallel ducts of equal width. The ducts in the middle honeycomb form ducts (25) leading to the inside of the bag (3) for the vapour to be condensed. The ducts in the boards on the outside form feeding ducts (26) for the vapour to be condensed. Pref. the ducts (25) are vertical whereas the ducts (26) run obliquely from one end of the strip to the other. The honeycomb strip at the lower end of each bag is similar to that at the upper end. However, the middle board contains ducts (31) which lead obliquely towards the end (30) of the strip and communicate with the ducts (12) sealed inside the bag. These serve as outlet ducts for the condensed liquid. The outer ducts (32) are vertical and serve as outlet ducts for any liquid remaining unvaporized and running down the outside surfaces of the bag.

USE/ADVANTAGE - The appts. produces potable water from sea water. It may also be used to concentrate suspensions, e.g. waste waters from bleaching in pulp mills. Clogging of ducts does not occur. (Dwg.1/6)
